PATENT APPLICATION of

Applicant: Inga et al.

Docket: IS3

Proposed Art Unit: 2612

Proposed Class: 358/403

Medical Image System with Progressive Resolution

This application is a continuation of US Patent Application 08/206,525, which was filed on March 4, 1994 as a division of US Patent Application Serial Number 07/915,298, ^{filed JULY 20, 1992} now US 5,321,520.

BACKGROUND OF THE INVENTION

Storage and retrieval systems for medical image data such as X-ray films, CAT scans, angiograms, tomograms and MRI are commonly antiquated. For example, when image films are used in the operating room, the physician must display these photo films on a light box.

Moreover, due to the diffuse responsibilities of multiple attending physicians and treatment sites, image data for patients with complex conditions is often lost, or at best, difficult to find when needed. Hospitals maintain large "file rooms" to store bulky patient image data films. In a complex situation in which several folders are needed, a file's weight can build up to 7 kg. It has proven time consuming to obtain image data from file rooms due to administrative backlogs, to lack of specialized filing personnel and to misfiling.

2

1 Typically, the physician examines the patient in his
2 office after the radiographical studies have been made in a
3 hospital or diagnostic facility. These films and the
4 information contained therein are often unavailable at the
5 time of the examination. Thus, there is a need for remote
6 access to these image data for rapid patient assessment and
7 therapy recommendation.

8 U.S. 4,603,254 teaches a stimuable phosphor sheet
9 carrying a radiation image stored therein scanned with
10 stimulating rays. The light emitted from the stimuable
11 phosphor sheet in proportion to the radiation energy stored
12 therein is detected and converted into an electric signal
13 converted to a digital signal. Digital data is created to
14 reproduce the radiation image for use in diagnosis and
15 storage.

16 U.S. 4,764,870 describes a system for transferring
17 medical diagnostic information from the diagnostic site to
18 remote stations. An internal analog video signal from
19 imaging diagnostic equipment such as a CAT scanner or MRI
20 equipment, is converted to an analog video signal of
21 different, preferably standard, format that is stored and
22 transmitted in the reformatted image information to the
23 remote terminal. The received signal is stored, decoded and
24 applied in appropriate analog video form to an associated CRT
25 display for reproduction of the diagnostic images.

26 U.S. 5,005,126 shows a system for transferring medical
27 diagnostic information from the diagnostic site to remote
28 stations similar to that found in U.S. 4,764,870.

29 U.S. 5,019,975 teaches a method for constructing a data
30 base in a medical image filing system comprising the steps or
31 recording information indicating the time at which each
32

1 medical image is recorded and a rank of importance for each
2 medical image as image retrieval signal data for image
3 signals corresponding to each medical image; recording the
4 number of times the image signals corresponding to each
5 medical image have been retrieved as image retrieval signal
6 data and incrementing the number each time the image signals
7 are retrieved; and when the data base is full of image
8 retrieval signal data, deleting the image retrieval signal
9 data corresponding to the image signals of the medical image
10 in which at least (1) the time at which the medical image was
11 recorded earlier than a predetermined time and (2) the rank
12 of importance of the medical image is lower than a
13 predetermined value.

14 U.S. 4,611,247 describes a radiation image reproducing
15 apparatus to read a radiation image from a first recording
16 medium as a visible image. Input devices of the apparatus
17 enter data which are associated with a method of exposing an
18 object to a radiation and object's exposed part. In response
19 to the input data, a processing condition determining unit
20 determines conditions optimum for a gradation processing and
21 a spatial frequency processing. A processor system is
22 provided for reading the radiation image stored in the first
23 recording medium and processing the radiation image on the
24 basis of conditions which the processing condition
25 determining unit determines in response to the input data
26 associated with the radiation image.

27 U.S. 4,750,137 discloses a method and a computer program
28 for performing the method for optimizing signals being
29 exchanged between a host unit and an addressable-buffer
30 peripheral device. The program optimizes an outgoing signal
31 from the host unit by (1) creating an updated-state map
32

1 representing the state of the peripheral device buffer
2 expected to exist after processing by the peripheral device
3 of the outgoing signal, (2) performing an exclusive-or (XOR)
4 operation using the updated-state map and a present-state map
5 representing the existing state of the buffer, and (3)
6 constructing and transmitting a substitute outgoing signal
7 which represents only changes to the buffer, and in which all
8 premodified field flags are turned off. Position-dependent
9 characters, such as attribute bytes, are translated into
10 nondata characters prior to incorporation into a map, and are
11 retranslated into their original form for use in the
12 substitute signal.

13 U.S. 4,858,129 teaches an X-ray CT apparatus in which a
14 plurality of dynamic tomographic images obtained by
15 repeatedly photographing a region of interest of a subject
16 under examination are stored in an image memory for
17 A subsequent ^{display} ~~display~~ on a display device. A processing device
18 extracts data of pixels along a certain line common to all of
19 the tomographic images and stores the pixel data in the image
20 memory, in the order of photographing time of the tomographic
21 images, thus forming a time sequence image formed of
22 picked-up pixels. The processing device reduces a
23 tomographic image and the time sequence image and rearranges
24 the reduced images in one frame area of the image memory for
25 simultaneous display thereof on the display device.

26 U.S. 5,021,770 discloses an image display system having
27 a plurality of CRT display screens. The system is of the
28 type in which a number of images of specific portions of a
29 patient having a specific identification code are selected
30 from among a multitude of X-ray image taken by a plurality of
31 shooting methods, and when the regions or interest are
32

1 specific, a plurality of appropriate images are further
2 A selected using the previously stored ^{amplitude} ~~attitude~~ values for the
3 regions and shooting methods and displayed on the plurality
4 of CRT display screens. In order that the segments to be
5 inspected can be pointed to on the screen on which the image
6 of the patient is displayed, a memory is provided which is
7 adapted to previously store codes corresponding to the
8 specific image of the patient and to specify the respective
9 regions of the image in such a manner that they correspond to
10 the pixel positions of the image.

11 U.S. 4,879,665 teaches a medical picture filing system
12 composed of a picture data memory device, a picture data
13 input-output device for inputting/outputting the picture
14 data, a retrieving device for storing the picture data into
15 A the memory device and ^{extracting} ~~extracing~~ it therefrom on the basis of
16 retrieving data, a retrieving data input device for inputting
17 the retrieving data into the retrieving device, a retrieving
18 data storing device for storing the retrieving data, the
19 retrieving data being classified by block of information
20 obtained in one-time examination. When medical pictures are
21 filed, retrieving data collected for each examination is
22 utilized for reducing the amount of retrieving data, while
23 when reproduced, retrieval is carried out for each one-time
24 examination thereby shortening the time required for
25 retrieval.

26 In light of recent advances in computer data basing,
27 digitization and compression of image data, image enhancement
28 algorithms and cost effective computer technology, the means
29 for improved storage and retrieval of vital patient image
30 data is now possible.

31 Such system should include the following major features:
32

1 1) means to more compactly store and more efficiently
2 retrieve image data and automatically identify the data by
3 patient name, image type, date and the like;

4 2) means for physicians to quickly and remotely access
5 particular patient image data at the medical facility even if
6 archived at several different locations;

7 3) means to prevent loss of vital image data due to
8 ordinary human handling and misplacement errors;

9 4) means to quickly and affordably access image data
10 from the physician's office;

11 5) means to enhance the medical images by both contrast
12 enhancement and zooming for improved diagnostics and/or
13 surgical guidance; and

14 6) means to quickly and conveniently access image data
15 and display on a large screen in the operating room with any
16 desired enhancement or expansion.

17 As described more fully hereinafter, the present
18 invention provides means to accomplish these goals. The
19 system uses both general purpose system elements well known
20 to those practiced in electronic arts and specific elements
21 having significant novelty.

SUMMARY OF THE INVENTION

The present invention relates to an automated high definition/resolution image storage, retrieval and transmission system capable for storing, transmitting and displaying medical diagnostic quality images for use with medical X-ray films or the like.

The system comprises means to process the image data from patient imaging to physician usage. The major or significant processing stages are described hereinafter. Specifically, the major steps in the image data flow include:

PATIENT RADIOGRAPHY: The patient's body is imaged and a film is exposed as in an X-ray room, MRI or CAT scan lab.

FILM PREPARATION: The film(s) is developed to create a visible image with OCR readable patient identification information superimposed thereon.

FILM INTERPRETATION: Commonly, a radiologist drafts an opinion letter for the film(s). This document preferably includes an optical character reader, or OCR, readable patient identification label or standard marking area.

IMAGE SCANNING & DIGITIZING SUBSYSTEM: A scanner subsystem digitizes each patient image film and/or document on a high resolution scanner. This digitized data is transmitted by a local high speed data link to a separate or remote master storage unit. Patient identification information is read from a standard format on each file by OCR techniques and efficiently stored with the digitized image data. Enhanced scanner resolution and gray scale requirements are provided. Further, to reduce data rate requirements, data compaction or compression is accomplished within the scanner subsystem.

1 To back-up possible data link down time or scanner down
2 time, the scanner subsystem may include a CD-ROM data storage
3 drive so that image data may continue to be digitized. The
4 CD-ROM disk may then be manually delivered to the file room
5 unit for subsequent use.

6 In an optional embodiment, the digitized data of one or
7 two images may be written to a compact semi-conductor memory
8 card "RAM Cards". This form of data storage may be used to
9 send selected images for special purposes such as when the
10 image data is needed in another city for second opinion
11 purposes.

12 At this point in the image data flow, there is a split
13 in which the original film data is stored as a "master" in a
14 file room and the image disk is made available for active
15 "on-line" use in an image storage and retrieval subsystem.

16 FILM FILING: The patient image films may be placed in
17 the industry standard 14 by 17 inch brown paper folders and
18 placed on conventional filing shelves. However, it is
19 preferred that older films be tagged and stored off-site to
20 reduce the current excessive bulk of films in many hospital
21 file rooms. The system would now make this practical since
22 the original films would seldom need to be accessed.

23 In the preferred embodiment of the system, the patient
24 may have his entire image data collected and written to one
25 or more of the storage CD-ROM disks for archiving at the
26 hospital.

27 IMAGE STORAGE AND RETRIEVAL SUBSYSTEM: This subsystem
28 is a remotely controllable, automatically accessible image
29 data subsystem to store and automatically retrieve,
30 on-demand, the compressed digital information contained on
31 the CD-ROM disks.
32

1 The image storage and retrieval subsystem has a
2 high-speed data link connection to the scanning and
3 digitizing subsystem and has a write drive recording
4 mechanism which is dedicated to receiving the data from the
5 scanning and digitizing subsystem. This CD-ROM write drive
6 can operate without interrupting remote access operations.

7 Remote access may be made to the image storage and
8 retrieval subsystem by a variety of telecommunication links.
9 Access will be granted only if a valid user code has been
10 presented. By means of several read-only CD disk drives and
11 electronic buffering, virtually simultaneous access can be
12 granted to several or more users.

13 As explained more fully hereinafter, the medical image
14 disk will contain relatively huge quantities of data making
15 it impractical to send over conventional data communication
16 links without very efficient data compression technology.
17 While there are a variety of data compression techniques
18 available, none are well tailored to this application. Thus,
19 a novel compression means are in the a remote telecommunication
20 access subsystem.

21 TELECOMMUNICATION SUBSYSTEM: Occasionally circumstances
22 may warrant manually making an extra copy of the patient's
23 image files to be physically delivered to an authorized
24 requester. However, for the system to fulfill broad service
25 to the health care industry it must be able to efficiently
26 telecommunicate image files to remote locations both cost
27 effectively and within a reasonable time interval.

28 A novel medical facsimile technology is in the preferred
29 embodiment which works interactively with a remote requester
30 to send only what is needed at acceptable resolutions, and
31 the presented image is progressively updated as the
32

1 communications connection is maintained until the resolution
2 limits of the user display are reached, after which time,
3 other images are either sent or further enhanced.

4 The specific technical means for accomplishing this uses
5 the following novel technologies: a) guided image selection &
6 transmission (GIST); b) progressive image enhancement (PIE);
7 c) display compatible resolution (DCR); d) hexagonal pattern
8 classification compression (HexPac) and e) run length coding
9 (RLC), RLC is well known to those skilled in the arts.

10 It appears practical to send immediately useful patient
11 data in less than one minute over a phone line (9600 baud)
12 whereas it take many hours by conventional coding and
13 transmission means. When wide-band telecommunications as
14 satellite, fiber optic, micro-wave links becomes more
15 generally available at affordable prices, then the more
16 complex data compression techniques described here will be
17 less important, but until that time, these types of
18 techniques are believed essential to overall system success.

19 This combination of technologies to efficiently compress
20 the image data and transmit remotely comprises the
21 telecommunication access subsystem. In practice, these
22 technologies may be implemented for the most part with
23 available computer modules although several special signal
24 processor boards are needed.

25 REMOTE DISPLAY TERMINAL: The quality of the image
26 available to the user is limited or determined by the
27 receiving presentation terminal or monitor. Two specific
28 presentation terminal types are envisioned in the preferred
29 embodiment of the system, a modified personal computer
30 terminal for use in a physician's office, hospital nurses'
31 station and the like, and a large screen presentation
32

1 terminal with remote controlled interaction primarily for
2 operating room use.

3 Both terminals have means to show the available patient
4 directory of images, and means to select an image,
5 enhancement and zoom on selected areas. Image enhancement
6 has heretofore been impractical for film based images and
7 thus much subtle but important pathological information has
8 been largely lost. This is especially true of X-ray data.
9 The ability to enhance subtle contrasted tissues areas is
10 considered to be an important feature and benefit of the
11 system.

12 An optional high-resolution printer (300dpi or better)
13 permits the physician to print out selected images. This
14 will be especially valuable when the physician expands and
15 enhances selected critical image areas since a cost effective
16 printer would otherwise not have adequate gray scale or pixel
17 resolution to give diagnostically useful output.

18 Each terminal consists of a standard high performance
19 personal computer with one or more data source interfaces
20 such as RAM card, CD-ROM disk or data modem, a decompression
21 graphics interface circuit and graphics display. The large
22 screen presentation terminal has a large screen display for
23 easy viewing for a surgeon who may be ten or more feet
24 distant. The large screen presentation terminal also has an
25 optional remote control so that an attending technician or
26 nurse can scroll images, enhance and zoom, at the surgeon's
27 request.

28 A keynote of each terminal design is a very simple user
29 interface based upon a limited selection menu and obviously
30 pointed-to graphical icons.
31
32

1 The invention accordingly comprises the features of
2 construction, combination of elements, and arrangement of
3 parts which will be exemplified in the construction
4 hereinafter set forth, and the scope of the invention will be
5 indicated in the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

For a fuller understanding of the nature and object of the invention, reference should be had to the following detailed description taken in connection with the accompanying drawings in which:

Fig. 1 is a functional block diagram of the entire system of the present invention.

Fig. 2 is a functional block diagram of the image scanning and digitizing means.

Fig. 3 is a functional block diagram of the image data storage and retrieval means.

Fig. 4 is a perspective view of the image data storage and retrieval means.

Fig. 5 is a functional block diagram of the telecommunication means.

Fig. 6 is a functional block diagram of the remote display terminal means.

Fig. 7 depicts the hexagonal pattern of the hexagonal compression method.

Fig. 8 depicts an actual hexagonal pattern from an X-ray film.

Fig. 9 depicts the selected predetermined hexagonal pattern most closely corresponding to the actual hexagonal pattern shown in Fig. 8.

Fig. 10 graphically represents the predetermined rotational orientations for the predetermined hexagonal patterns.

Fig. 11 graphically depicts a selected gray level slope of the selected predetermined hexagonal pattern of Fig. 9.

Fig. 12 depicts a single pixel from the predetermined hexagonal pattern.

1 Fig. 13 depicts a hexagonal pattern reconstructed by a
2 remote display terminal means corresponding to the actual
3 hexagonal pattern shown in Fig. 8.

4 Figs. 14-A through 14-H depict the predetermined set of
5 orthogonal gray level patterns.

6 Similar reference characters refer to similar parts
7 throughout the several views of the drawings.

1 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

2 As shown in Fig. 1, the present invention relates to an
3 automated high definition/resolution image storage, retrieval
4 and transmission system generally indicated as 10 for use
5 with medical X-ray film 12 or other documents to provide
6 simultaneous automated access to a common data base by a
7 plurality of remote subscribers upon request from the remote
8 subscribers.

9 The automated high definition/resolution image storage,
10 retrieval and transmission system 10 comprises an image
11 scanning and digitizing means 14 to transform the visual
12 image from the medical X-ray film 12 or other documents into
13 digital data, an image data storage and retrieval means 16 to
14 store and selectively transfer digital data upon request, a
15 telecommunication means 18 to selectively receive digital
16 data from the image data storage and retrieval means 16 for
17 transmission to one of a plurality of remote visual display
18 terminals each indicated as 20 upon request from the
19 respective remote visual display terminal 20 through a
20 corresponding communications network 21 such as a telephone
21 line, satellite link, cable network or local area network
22 such as Ethernet or an ISDN service for conversion to a
23 visual image for display at the remote requesting site.

24 To improve automation and tracking, a machine readable
25 indicia or label 22 containing key patient information may be
26 used in association with the medical X-ray film 12. As
27 shown, the machine readable indicia or label 22 is affixed to
28 the medical X-ray film 12 prior to scanning by the image
29 scanning and digitizing means 14 to provide file access and
30 identification. Furthermore, digital data from alternate
31 digitized image sources collectively indicated as 24 and file
32

1 identification may be fed to the image data storage and
2 retrieval means 16 for storage and retrieval.

3 Fig. 2 is a functional block diagram of the image
4 scanning and digitizing means 14 capable of converting the
5 visual image from the medical X-ray film 12 to digitized
6 image data for transmission to the image data storage and
7 retrieval means 16 over a bi-directional high speed data link
8 25. Specifically, the image scanning and digitizing means 14
9 comprises a film loading and scanning section and a data
10 compression and transmission section generally indicated as
11 26 and 27 respectively and a display and control section
12 generally indicated as 28. The film loading and scanning
13 section 26 comprises a film input loader 30, alignment and
14 sizing chamber 32, optical character reader 34 and film
15 scanner/digitizer 36 capable of at least 500 dots per inch
16 resolution 36; while, the data compression and transmission
17 section 27 comprises a data buffer memory 38, low-loss data
18 compression means 40, local data modem 42 and transmission
19 connector 44 to operatively couple the image scanning and
20 digitizing means 14 to the image data storage and retrieval
21 means 16. The low-loss data compressor 40 is also
22 operatively coupled to a compact disk data storage drive 46
23 capable of writing or storing compressed digitized patient
24 image data on a compact disk 48. The display and control
25 section 28 comprises a keyboard/control console 50, display
26 terminal 52 and control computer 54 which is operatively
27 coupled to the other components of the image scanning and
28 digitizing means 14 through a plurality of conductors each
29 indicated as 55. A film collector tray 56 may be disposed
30 adjacent the film scanner/digitizer 36 to receive the medical
31 X-ray film 12 therefrom following processing.
32

1 To reduce the approximately 238 Megapixels required to
2 digitize a 14 inch by 17 inch, medical X-ray film 12 with 700
3 dots or pixels per inch with a two byte level to a manageable
4 size without significant information loss, a linear gray
5 level prediction, modified run-length code generating logic
6 circuitry is embodied within the low-loss data compression
7 means 40 to dynamically compress the digitized data before
8 storage or recording. The image data is compressed with
9 acceptable diagnostic resolution loss. The low-loss data
10 compression means 40 measures the "local" slope of the pixel
11 gray level and continues to compare that estimated gray level
12 for up to an entire scan line until a pixel region is reached
13 which differs from the linear estimate by more than a
14 predetermined amount. The data actually sent for that region
15 consists of the slope of the line, actual level at the origin
16 of the slope line and the number of pixels comprising that
17 region. The circuitry will discard linear gray level slope
18 differences of the original film which can be reliably
19 determined to be noise or image "artifacts". A sudden one
20 pixel (if at 1000 dots per inch) dramatic change in gray
21 level could be rejected as dust or film noise for example.
22 The compressed data is a trade-off between complexity, speed
23 and minimum data loss to reduce the total data quantity
24 stored by a factor of approximately three. Thus, about 80
25 Megapixels of data may still have to be stored per 14 inch by
26 17 inch film image.

27 In the preferred embodiment, the bi-directional high
28 speed communications link 25 transmits the low-loss
29 compressed digitized data from the developing lab room to the
30 hospital file room where the image data storage and retrieval
31 means 16 will transfer and store the patient and image data
32 in a new patient file on a compact disk 48.

1 Two way communications between the image scanning and
2 digitizing means 14 and the image data storage and retrieval
3 means 16 minimizes data loss by insuring that a compact disk
4 48 be available to receive and store data. Moreover, the
5 compact disk data storage drive 46 with re-writable ROM
6 technology can record data even if communications with the
7 image data storage and retrieval means 16 is disrupted.
8 Thus the image scanning and digitizing means 14 can
9 automatically start writing data to the compact disk data
10 storage drive 46 as soon as a image data storage and
11 retrieval means 16 fault is sensed. The display and control
12 section 28 informs the operator of the system status.

13 In operation, the film lab technician may stack one or
14 more medical X-ray films 12 onto the input loader 30 as shown
15 in Fig. 2. A "read" button is depressed on the keyboard/
16 control console 50 and each film 12 is thereafter fed in
17 automatically, digitized and transmitted to the image data
18 storage and retrieval means 16 located in the file room. As
19 the reading of each film 12 is completed, the film 12 is
20 deposited into the film collector tray 56. System status,
21 number-of-films read logging and so forth are shown on the
22 display terminal 52.

23 Initially, the image scanning and digitizing means 14
24 positions the film 12 in the alignment and sizing chamber 32
25 on a precision carrying platen for subsequent optical
26 scanning. This platen contains optical sensors to sense the
27 exact film size so only the useful image area is digitized.
28 Once the film 12 is secured onto the movable platen, the film
29 12 is passed through the optical character reader 34 and then
30 to the film scanner/digitizer 36.
31
32

1 The patient data and image identification is first
2 recorded onto the remote CD-ROM file directory in the image
3 data storage and retrieval means 16 from the OCR "pass" and
4 then the compressed scanned image data is sequentially
5 written to a compact disk 48 by a CD write drive for storage
6 with the CD library storage of the image data storage and
7 retrieval means 16 as described more fully hereinafter as the
8 film 12 slowly passes through the film scanner/digitizer 36.

9 Specifically, the film scanner/digitizer 36 converts the
10 image to a digital representation of preferably at least a
11 700 dot per inch resolution. This digital data is
12 temporarily stored in the data buffer memory 38 where the
13 patient data from the optical character reader 34 and
14 corresponding digitized image data from the file scanner/
15 digitizer 36 are properly formatted for subsequent
16 compression and transmission to the image data storage and
17 retrieval means 16. The stored data is then accessed by and
18 compressed by the data compression means 40 as previously
19 described and transmitted through the local data modem 42 and
20 transmission connector 44 to the image data storage and
21 retrieval means 16 or a compact disk data storage drive 46.
22 The display and control section 28 permits the X-ray lab
23 staff to monitor system status, report quantity of documents
24 and films processed and allow for scheduling local recording
25 of image data on compact disks 48.

26 Figs. 3 and 4 show the image data storage and retrieval
27 means 16 to receive and store the low-loss compressed
28 digitized patient information and image data from the image
29 scanning and digitizing means 14 and to selectively transmit
30 the stored low-loss compressed digitized patient information
31 and image data to one or more of the remote visual display
32

1 terminal(s) 20 through corresponding telecommunication means
2 18 and corresponding communications network(s) 21 upon
3 request from one or more of the remote display terminal(s)
4 20.

5 The image data and retrieval means 16 is essentially a
6 central data storage library for medical subscribers to
7 remotely access and visually display patient data and
8 information.

9 As described hereinafter, the image data storage and
10 retrieval means 16 is robotically automated to minimize
11 hospital staff requirements. At any given time, it is
12 estimated that a typical hospital may have several hundred
13 active patients with requirements for physician access to
14 corresponding image files. An active patient may require one
15 to three compact disks 48. Thus, the image data storage and
16 retrieval means 16 should have sufficient means to store and
17 retrieve at least 500 compact disks 48.

18 Further, to minimize personnel requirements, the image
19 data storage and retrieval means 16 has a semi-automatic
20 log-in mechanism for updating the compact disk inventory and
21 an automatic mechanism for retrieving and reading the compact
22 disks 48 remotely via communication link interfaces similar
23 to juke box playback mechanisms. Except for the occasional
24 loading of new empty compact disks 48 and removal of inactive
25 compact disks 48, the operation of the image data storage and
26 retrieval means 16 is fully automatic, permitting authorized
27 access at any time.

28 As described more fully hereinafter, several playback
29 drives with electronic buffering are incorporated so that
30 essentially simultaneous access can be provided to several
31 remote requesting users. An optional duplicating CD write
32

1 drive and RAM-Card drive permits additional copies to be made
2 locally upon demand for either back-up or other use. The
3 image data storage and retrieval means 16 has an operator's
4 console/desk arrangement for file maintenance and duplicating
5 control by the hospital file room clerk. Control software is
6 a simple menu selection design so that relatively unskilled
7 personnel can maintain the central data storage library or
8 image data bank.

9 As shown in the functional block diagram of Fig. 3, the
10 image data storage and retrieval means 16 comprises a local
11 data modem 58 operatively coupled between the image scanning
12 and digitizing means 14 through the transmission connectors
13 44 and bi-directional high speed communication link 25, and a
14 selector or multiplexer 60. A format convertor 62 is
15 operatively coupled between the alternate digitized image
16 source(s) 24 such as CAT 64, MRI 66 and/or video 68 and
17 control computer 70 which is, in turn, coupled to a control
18 console 72 including a visual display and input means such as
19 a keyboard. The local data mode 58 is also coupled to the
20 hard disk (H/D) of the control computer 70 through a
21 conductor 71. The other components of the image data storage
22 and retrieval means 16 are coupled to the control computer 70
23 through a plurality of conductors each indicated as 73. A CD
24 write drive 74 is operatively coupled between the multiplexer
25 or selector 60 and an auto disk storage/retrieve mechanism 76
26 which is, in turn, operatively coupled to a CD library
27 storage 78, a manual load/purge box 80 and a plurality of
28 data retrieval and transmission channels each indicated as
29 81. Each data retrieval and transmission channel 81
30 comprises a CD reader drive 82 operatively coupled through a
31 corresponding data interface 84 to a corresponding
32

1 transmission connector 86. In addition, one of the CD reader
2 drives 82 is operatively coupled through a selector switch 88
3 to an optional CD write/RAM card drive 90 configured to
4 manually receive a compact disk 48 or RAM card.

5 As shown in Fig. 4, the CD library storage 78 comprises
6 at least one cabinet 200 to operatively house 800 compact
7 disks 48 arranged on four shelves each indicated as 202 and
8 the auto disk storage/retrieval mechanism 76 which comprises
9 a CD coupler 204 to engage and grasp a selected compact disk
10 48 and move horizontally on a support member 206 that moves
11 vertically on a pair of end support members each indicated as
12 208. An access door 210 permits movement of compact disks
13 48 to and from the cabinet 200. However, in normal
14 operation, "old" patient data is removed by writing collected
15 image data to a single compact disk 48 through the CD
16 write/RAM card drive 90 thus freeing internally disposed
17 compact disks 48 for new data. The CD write/RAM card drive
18 90 may also be used to collect a patient's image data on a
19 single compact disk 48 for use in the operating room's
20 display terminal. This obviates the need for a high speed
21 internal hospital local area network.

22 The computer associated with the CD robotic arm and
23 drive mechanism performs ordinary library maintenance
24 functions such as retrieval of outdated files, access
25 statistics, entry of access validation codes, and so forth.
26 This computer subsystem also handles data communication
27 interface functions.

28 Internal to the environmentally controlled cabinet 200
29 are a plurality of playback mechanisms (field expandable to
30 six) which are automatically controlled by the accessing
31 physicians via the coupled communications system. Yet
32

1 another CD-ROM write drive can record new data from the image
2 scanning and digitizing means 14 or perform library functions
3 such as consolidation of a patient's data from several
4 compact disks 48 to a single patient-dedicated compact disk
5 48.

6 The internal computer maintains a file log of which
7 compact disks 48 are empty and where each patient's image
8 data is stored by disk number and track on a disk location.
9 When the image scanning and digitizing means 14 requests to
10 down-load data, the auto disk storage/retrieval mechanism 76,
11 of the image data storage and retrieval means 16 retrieves
12 the "current" compact disk 48 which is being written with
13 data (if not already loaded), then loads the compact disk 48
14 into the CD write drive 74, and signals to the image scanning
15 and digitizing means 14 to transmit. Image data is then
16 recorded with a typical record time of 4 minutes for a
17 full-size, high density image.

18 Once the robotic arm has delivered the compact disk 48
19 to the CD write drive 74, the robotic arm is free to access
20 and place other compact disks 48 onto CD reader drive 82 as
21 commanded by its communications interface. The robotic arm
22 can find and place a disk 48 into the appropriate CD reader
23 82 in approximately 10 seconds. Thus, there is minimal
24 waiting time for disk access unless all CD readers drives 82
25 are in use.

26 As shown in Fig. 3, data is received through the input
27 transmission connector 44 to the CD write drive 74 through
28 the selector switch 60. Alternately, other image data from
29 other sources such as CAT scanners 64 or MRI medical
30 equipment 66 may be fed through the format convertor 62 for
31 storage on a compact disk 48. If the other image sources are
32

1 written to CD write drive 74, file identification data must
2 be supplied to the format convertor 62 from the control
3 computer 70.

4 The image file data received from the image scanning and
5 digitizing means 14 is directly written to free space on a
6 compact disk 48 in the CD write drive 74. No other data
7 compression or special formatting is required as the image
8 scanning and digitizing means 14 has performed these
9 functions. As new image data is received from the image
10 scanning and digitizing means 14 or another image source 24,
11 the image data is sequentially appended to the last file on
12 the compact disk 48 currently being written to. Thus, no
13 attempt is made to organize a single patient's image files
14 onto a single compact disk 48. However, each file received
15 is logged into the control computer 70 through the conductor
16 71. Therefore, the control computer 70 always knows what
17 disk location in the CD library storage 78 contains any
18 specified file. Once a compact disk 48 is filled with image
19 data, the auto disk storage/retrieve mechanism 76 removes the
20 compact disk 48 from the CD write drive 74 and stores the
21 compact disk 48 in an empty location in the CD library
22 storage 78.

23 The plurality of data retrieval and transmission
24 channels 81 service the data requests from subscribers. As
25 previously indicated, a single data retrieval and
26 transmission channel 81 includes the select switch 88 to
27 direct image file data to the optional CD write/RAM card
28 drive 90. By this means, all image data for an individual
29 patient may be collected on one or more selected compact
30 disks 48 for archiving or other use. However, normally, the
31 control computer 70 will automatically remove old image data
32

1 by removing the compact disk 48 from the CD library storage
2 78 and placing the compact disk 48 in the manual load/purge
3 box 80. The removal age and exceptions information are
4 selected by the system operator from the control console 72.

5 The control console 72 is also used to enter and
6 maintain subscriber access identification codes in an
7 "authorization file". This updated user authorization file
8 data is sent through a transmission connector 92 to the
9 telecommunications means 18 internal computer memory accessed
10 by the control computer 70 as needed to accept or reject
11 subscriber data link access requests. The user authorization
12 file normally residing in the telecommunications means 18 may
13 be remotely updated by authorized persons.

14 The number of data retrieval and transmission channels
15 81 depends on intended subscriber demand. The image data
16 storage and retrieval means 16 is modular and may be upgraded
17 as demand increases. Each data interface 84 operates
18 cooperatively with the telecommunications means 18 to send
19 only as much information as the telecommunications means 18
20 can compress and transmit to a remote visual display terminal
21 20 of a requesting subscriber in a given time interval.
22 Thus, the interface is an asynchronous block-buffered type.

23 Since the entire system 10 is designed to provide easy
24 and quick access to a patient's medical images, it is vital
25 that these images be transmitted to a variety of locations in
26 a timely and cost effective manner and further data
27 compression is imperative. The telephone network is still
28 the most commonly available network but has a severe data
29 rate limitation of about 1200 bytes per second (9600 baud).
30 While other high speed telecommunication channels such as
31 time-shared cable, satellite link may eventually become
32

1 commonly available, for the immediately foreseeable future,
2 the "phone" network must be used if system 10 is to be
3 practical today.

4 As noted earlier, a typical medical image may be stored
5 as 119 megabytes of data. At 1200 bytes per second, it could
6 take 27 hours to completely transmit the already compressed
7 medical image data. This is obviously unacceptable. To
8 overcome this obstacle, the telecommunications means 18 as
9 shown in Fig. 5 utilizes five distinct data handling
10 technologies to achieve useful data image transmission in
11 less than one minute:

12 (1) Guided Image Selection and Transmission or GIST
13 depends upon interactive use by the physician to identify
14 what portions of an image are needed for enhancement or
15 better resolution. Thus the data actually transmitted to the
16 subscriber's visual display terminal 20 is guided by the
17 subscriber observing the image. In particular, once the user
18 has an image displayed on his or her visual display terminal
19 20, the user may outline a specific region of interest such
20 as a lesion or ^{tumorous} ~~tumorous~~ growth for more detailed study. The
21 operator may select this region using a "mouse" or light pen
22 or similar well-known computer display terminal peripheral
23 device. Having selected this region, the visual display
24 terminal 20 will display the more detailed pixel data be sent
25 on this region. The telecommunications means 18 will
26 continue to send further precision data until the natural
27 resolution limits of the display are reached or all available
28 data is sent and received. This process of expanding an
29 image region is known as "zooming" in computer-aided design
30 systems. The novel feature here is that the image is further
31 refined in resolution when "zoomed". The means for doing
32

1 this and knowing when to "stop" further pixel transmission is
2 defined by the PIE and DCR technology described hereinafter,

3 (2) Progressive Image Enhancement or PIE utilizes the
4 transmission time from the instant a first "crude" image is
5 presented to the subscriber to the present time of
6 observation to progressively enhance the quality of the
7 presented image. The longer the user observes a selected
8 image, the "better" the image becomes in the sense of pixel
9 resolution and quantity of gray levels. In the preferred
10 embodiment, hexagonal pixel groups are first transmitted
11 using the HexPac pattern compression technology described
12 hereinafter. Once a full terminal screen display has been
13 made composed of these hexagonal patterns, then the
14 telecommunications means 18 transmits more precise pixel
15 detail. First all pixels located on the periphery of each
16 hexagonal group are updated with their exact gray level
17 values and thereafter, all inner pixels are similarly
18 updated. If the display terminal's resolution is less than
19 the 1000 dots per inch of the source image data, then pixel
20 groups are sent, such as a square of four pixels, which match
21 the display resolution and "zoom" expansion selected. This
22 display matching technique is further defined hereinafter as
23 DCR,

24 (3) Display Compatible Resolution or DCR transmits
25 information about the user's terminal 20 back to the
26 telecommunications means 18. Only data with a resolution
27 compatible with that terminal 20 will be sent. Any excess
28 data-link connect time can be used to send other image data
29 which is likely to be requested or has been pre-specified to
30 be sent.
31
32

1 (4) An image pattern compression method comprising a
2 Hexagonal Pattern Classification or HexPac exploits the two
3 dimensional nature of images. The data received by
4 telecommunications means 18 is first uncompressed and placed
5 into a multi-scanline digital buffer. This image data is
6 then divided up into hexagonal cells and matched against
7 predefined patterns. Many fewer bits of data can be used to
8 A represent these predefined patterns, thus substantially
9 compressing the image data for phone-line transmission. The
10 pixels of these hexagonal patterns may easily be "refined" by
11 the PIE technology described earlier. If the DCR subsystem
12 determines that the user terminal has a pixel area of, say,
13 1500 by 1000 dots, then the HexPac technology recreates a new
14 super pixel which is the average gray level of all actual
15 pixels within that super pixel area. This immediately
16 reduces the quantity of pixels to be sent (to only 1500 by
17 1000 pixels). Without further data compression, this
18 quantity of data would still require about 26 minutes of data
19 transmission time at 9600 baud, the highest available phone
20 network data rate.

21 (5) Run length coding or RLC permits data to be
22 compressed by specifying how many pixels have the same gray
23 level in a sequence or "run length" of scanning. The image
24 data sent by a CD reader drive 82 to telecommunications means
25 18 is compressed with run-length coding but is nearly
26 loss-less in the duplication of the original film data. To
27 substantially reduce the quantity of data needed to send an
28 acceptable medical image to a remote user terminal 20 over
29 the data-rate limited phone-line modem, a "lossy" compression
30 is used. Since the PIE and DCR techniques described earlier
31 will eventually provide any degree of diagnostic image
32

1 integrity desired, it is believed acceptable to initially
2 transmit a "lossy" image provided it gives adequate
3 resolution for the user to begin the analysis and guided
4 image selection. Many fewer bits can describe this "run" of
5 similar gray levels thus compressing the amount of data sent.
6 This technique is well known and often used in facsimile
7 transmission. A one dimensional RLC is incorporated in the
8 preferred embodiment but since HexPac elements are being
9 coded, it can be considered more accurately a quasi two
10 dimensional RLC compression.

11 Fig. 5 is a functional block diagram of the tele-
12 communications means 18 including a control computer 94
13 operatively coupled to the image data storage and retrieval
14 means 16 through a transmission connector 96. The various
15 components of the telecommunications means 18 including a
16 status panel 98 with a plurality of system indicators each
17 indicated as 99 and a plurality of data compression channels
18 each generally indicated as 100 coupled to the control
19 computer 94 by a plurality of conductors each indicated as
20 101.

21 Each data compression channel 100 comprises a
22 transmission connector 86, a communications data interface
23 102, a first compression processor or means 104 including
24 logic means to generate the GIST and DCR data compressions
25 and corresponding first data memory 106, a second compression
26 processor or means 108 including logic means to generate the
27 PIE and HEXPAC data compressions and corresponding second
28 data memory 110 and a third compression processor or means
29 112 including logic means to generate the RLC data
30 compression and corresponding third data memory 114, a
31 corresponding modem 116 and a transmission connector 118.
32

1 The control computer 94 coordinates or controls data
2 flow to and from the plurality of data compression channels
3 100 through the transmission connectors 86 and 118
4 respectively. Validated subscriber image data requests are
5 transmitted to the image data storage and retrieval means 16
6 which searches the image library file 78 for availability of
7 the requested compact disk 48. If available, the image data
8 storage and retrieval means 16 loads the appropriate disk 48
9 from CD library storage 78 into a CD reader drive 82 and
10 informs telecommunications means 18 through the transmission
11 connector 96 to the control computer 94 that a specific data
12 interface 84 has data available to be transmitted through the
13 corresponding transmission connectors 86. Once a subscriber
14 transaction has been turned over to a specific data retrieval
15 and transmission channel 81, the data compression channel 100
16 receives the data therefrom unless commanded to stop by a
17 feedback control line. The data interface 102 is used to
18 inform the CD reader drive 82 as to what portion of the image
19 is requested by the first compression means 104. Generally,
20 the complete image is first requested. Thus the CD reader
21 drive 82 is requested to read the image data from the start.

22 The data is temporarily stored in the first data memory
23 106. Here the pixel data is first expanded from the RLC code
24 into uncompressed pixel data. This is only done on a
25 relatively few number of scan lines - about one tenth of an
26 inch height of original image data. This uncompressed data
27 is then remapped by the first compression means 104 into
28 "larger" pixels whose average intensity is the average of all
29 combined pixels compatible with the display resolution
30 receiving remote visual display terminal 20. This "super
31 pixel" data is then fed to the second data memory 110. The
32

1 super pixel data in memory 110 is then processed by the
2 second compression means 108. Initially, the lowest
3 resolution image will be transmitted to rapidly form a useful
4 remote image on the requesting remote visual display terminal
5 20 through a communications network 21. This will be done by
6 combining super pixels in the second data memory 110 into
7 hexagonal patterns which approximate the group of super
8 pixels. These HexPac data packets are then sent to the third
9 data memory 114. There the HexPac data packets are further
10 compressed by the third compression means 112. These packets
11 of run-length coded HexPac data packets are then transmitted
12 through the corresponding modem 116 and transmission
13 connector 118 over the selected communications network 21.
14 The modem 116 includes state of the art error control
15 techniques such as block retransmission when a remote error
16 has been detected. Thus, data transmission is essentially
17 error-free as needed for compressed data handling.

18 The control computer 94 includes circuitry means to
19 monitor the activity of each data channel. The
20 identification of each subscriber is logged along with the
21 total connect time for billing purposes. Thus the control
22 computer 94 generally coordinates the plurality of
23 communication links and their connections to the particular
24 data retrieval and transmission channel 81 within the image
25 data storage and retrieval means 16 as well as granting
26 access and performing connection accounting tasks. The
27 status panel 98, connected to the control computer 94 is used
28 to aide in system debug and indicate operation of the data
29 compression channels 100. The status panel 98 would not
30 normally be used by hospital personnel but by system service
31 technicians.
32

1 The control computer 94 also has a permanent memory such
2 as a hard disk to record subscriber usage data and internally
3 sensed hardware problems. This data may be downloaded on any
4 of the transmission connectors 118 when a correct
5 authorization code has been received. Thus, the servicing
6 company can acquire subscriber usage information remotely for
7 billing purposes and system diagnostic purposes.

8 The preferred embodiment of the telecommunications means
9 18 uses modular communication channel hardware. Thus, the
10 module may be customized to function with any type of
11 communication channel such as satellite links, cable networks
12 or a local area network such as Ethernet or ISDN services.

13 It is important to note that all communications is
14 bidirectional so that if, say, a remote visual display
15 terminal 20 should become temporarily "overloaded" with image
16 data due to decompression processing delays or due to a
17 detected data error, then, the remote visual display terminal
18 20 may request that data transmission be stopped or a block
19 of data be repeated until it is received correctly.

20 Fig. 7 graphically shows a hexagonal group of the
21 hexagonal compression method comprising a group of square
22 image pixels partitioned into a hexagonal group. The pixels
23 are numbered for convenience of reference from the inside to
24 the outside in a clock-wise manner. Each hexagonal group or
25 packet comprises 24 super pixels as earlier described but
26 other numbers are possible. It is assumed that each pixel is
27 gray level coded using 2 bytes of data. Thus, the hexagonal
28 group requires (24X2) 48 bytes of data to fully represent the
29 24 super pixels comprising the image pattern at the user
30 terminal 20.
31
32

1 Fig. 8 shows a typical pattern as may occur in a region
2 of an X-ray film 12. The method predefines a group of likely
3 patterns, one of which is represented as a "best" match as in
4 Fig. 9 with the actual pattern in Fig. 8. As shown in Figs.
5 14A through 14H, there are 8 possible predetermined
6 representative gray level patterns represented by 3 bits.
7 These patterns are specifically selected to be essentially
8 A uncorrelated with each other even^F rotated relative to each
9 other. As shown in Fig. 10, these patterns may be rotated
10 through 8 equal angles (another 3 bits of data) to best match
11 the actual pattern. Rotation angle "1" is shown in Fig. 10
12 as the best match for the given example. Thus far, six bits
13 have been used to approximate the actual pattern of Fig. 8.
14 As shown in Figs. 14A through 14H, each fictitious pattern
15 includes a dark and light regions and origin. Although Fig.
16 11 discloses a straight gray level slope corresponding to the
17 pattern shown in Fig. 14A, the gray level slope will vary
18 with the fictitious pattern. For example, the gray level
19 slope of the fictitious pattern shown in Fig. 14D would
20 closely approximate a V shape.

21 Fig. 11 shows how the gray level slope may be discretely
22 selected to best match the slope of the actual pattern. Two
23 bits are used to approximate this slope.

24 Fig. 12 shows that one particular pixel, such as the
25 darkest pixel, has been selected to be fairly precisely gray
26 level represented by means of 8 bits (256 gray levels).

27 The total bits required to approximate the actual
28 pattern is 16 or two bytes. Fig. 13 shows how this
29 fictitious or reconstructed pattern may be reproduced at the
30 user terminal 20 when decoded.
31
32

1 In this example, only two bytes were required to
2 represent "adequately" an original 48 bytes of image data.
3 Thus, a 24 to 1 compression ratio has been achieved.
4 Further, run-length encoding (RLC) may be used on these
5 HexPac groups to further reduce redundant spans of white and
6 black. It is estimated that the combined compression ratio
7 of HexPac and RLC on the super-pixel image is about 36 to 1,
8 for this particular set of parameters. This combined
9 compression technology reduces data transmission time (at
10 9600 baud) to approximately 43 seconds for an initial useful
11 medical image.

12 For medical images, further enhancements through the PIE
13 compression should favor the elimination of artificial lining
14 between hexagonal patterns first. As the user continues to
15 view the same image, then the PIE compression will
16 progressively improve the gray level integrity by updating
17 all number 24 pixels to 8 bits of gray level resolution and
18 updating all number 23 pixels to 8 bits of gray level and so
19 forth for all remaining pixels in descending order. This
20 process takes about 10 minutes at 9600 baud to update all
21 peripheral hexagonal pixels and about 20 minutes total for
22 all pixels.

23 If the user continues to observe or request further
24 image resolution, the telecommunication means 20 causes each
25 pixel gray level to be updated by one additional bit in
26 descending order again until the full 16 bits of gray level
27 is received and stored at the terminal 20 for each super
28 pixel. Each doubling of gray level resolution takes between
29 1 and 2.6 minutes at 9600 baud depending on the run length
30 statistics of the gray levels.
31
32

Fig. 6 is a functional block diagram of a remote visual display terminal 20 to be operatively coupled to one of the data compression channels 100 of the telecommunication means 18 by a communications network 21 and a transmission connector 118. The visual display terminal 20 comprises a data communications modem 120 operatively coupled to a control computer 122 and RLC decompression means 124. The RLC decompression means 124 is, in turn, operatively coupled to a memory 126, a PIE bypass 128 and a pattern select and modifier 130 which is operatively coupled to a HexPac pattern ROM 132 and the control computer 122. A memory 134 is operatively coupled between the PIE bypass 128 and pattern selector and modifier 130 and a display drive 136 which is operatively coupled to an image display 138. In addition, an image enhancing processor means 139 including circuitry to generate edge contrast enhancement, gray level contrast enhancement by means of gray level region expansion or differential gray level tracking and gray level enhancement or other state of the art image enhancement method well known to those skilled in the art. The control computer 122 is operatively coupled to an interface 140 to a first control or selector means 142 and a second control or selector means including a radio receiver 144 and signal command decoder 146 for use with portable keyboard transmitter 148. In addition, an optional CD read/write drive 150 may be provided for use with a compact disk 48.

The modem 120 has built-in compatible error correction technology to communicate with corresponding transmitting data compression channel 100. After the user has selected the image data storage and retrieval means 16 and validated authority by swiping through an identification magnetic card

1 152 or otherwise through a magnetic card reader 154 entered
2 an assigned security code, the operator may select a patient
3 and one or more image files presented to him on the display
4 screen 138. Selection is accomplished by a touch-screen
5 overlay on the first control or selector means 142 or by the
6 keyboard transmitter 148 of the second control or selector
7 means.

8 Once one or more images have been selected by the user,
9 the modem 120 writes image data to the temporary memory 126
10 which is actively accessed by the RLC decompression means
11 124. This decompressed data describes the HexPac patterns or
12 packets as stripes of the image running, for example,
13 sequentially from left to right. These Hexpac pattern
14 specifications, typically 2 data bytes or 16 bits are then
15 routed to a pattern selection processor 130 which accesses
16 the predefined patterns from Read-Only Memory device 132.
17 Each pattern is then rotated and gray-level modified by
18 processor 130 according to the HexPac 16 bit pattern
19 specification received from the RLC decompression means 124.
20 Each modified pattern is then written to a graphics display
21 memory circuit 134. As the graphics display memory circuit
22 134, develops the pattern data, the display driver 136 and
23 image display 138 show the image on the screen as it is
24 received. In this manner, the entire "first pass" medical
25 image is painted on the image display 138 screen.

26 If the user makes no further intervention, then once the
27 image is fully displayed on this "first pass", then the
28 progressive image enhancement technology requests pixel
29 enhancement data. This enhancement data bypasses pattern
30 selector and modifier 130 and is routed through the PIE
31 bypass 128. In the PIE bypass 128, the enhanced pixel
32

1 information is directed to the correct graphic memory
2 locations in the graphics display means circuit 134'. Thus,
3 the display driver 136 and image display 138 are continually
4 resolution enhanced.

5 If the image is fully enhanced to the limits set by the
6 DCR in the control computer 122, the image storage and
7 retrieval means 16 is directed by the control computer 122 to
8 begin sending new image data on the next selected image and
9 begin storing this image data in a second graphics display
10 memory circuit 134". This second data memory 134" can hold
11 A one ^{or} more images and may be selected immediately by the user
12 when he is finished inspecting an earlier image. The user
13 may further direct by touch screen command 142 that these be
14 stored in the computer's hard disk or archived by the
15 optional CD read/write drive 150.

16 The user may at any time select a portion of the
17 displayed image for further expansion by enabling or
18 selecting the Guided Image Selection & Transmission (GIST)
19 circuitry in the control computer 122 or image enhancement
20 through the image enhancing processor means 139. This may be
21 accomplished either by touch screen control means 142 or the
22 second remote control means 144/146/148. This remote
23 keyboard and transmitter unit 144/146/148 duplicates the
24 on-display simulated push-buttons of the touch screen control
25 means 142. Coded command signals sent by 148 are received by
26 radio receiver 144 and decoded by 146. These commands are
27 then accepted by control computer 122 as though they were
28 normal keyboard commands.

29 The user may terminate a session with the image data
30 storage and retrieval means 16 at any time by *selection of*
31 stop and escape command. While a printer is not shown in
32

1 this description, it can be an optional addition to terminal
2 20.

3 In summary, the image data storage and retrieval means
4 16 selects the first image and writes that data to a
5 temporary memory buffer in the telecommunication means 18.
6 Information about the subscriber's terminal is uploaded to
7 the telecommunications means 18 so that the Display
8 Compatible Resolution (DCR) logic circuitry knows when to
9 stop sending added data for the requested first image. A
10 special interactive compression computer then compresses this
11 first image data using the HexPac circuitry and sends that
12 data over the data link modem to the subscriber terminal 20.
13 Error detection and correction methods will generally be used
14 in this communications link protocol.

15 Once a first "crude" image is sent to the subscriber
16 visual display terminal 20, then the Progressive Image
17 Enhancement (PIE) circuitry begins to send additional data to
18 further refine the resolution of each hexagonal pixel region.
19 If no further guidance is given by the subscriber, the PIE
20 will continue to refine the picture's resolution until its
21 natural limit is sent for the terminal 20. Thereafter, the
22 PIE will begin sending image data from the second specified
23 film and loading it into yet another memory buffer. Thus,
24 the data link connection is always transmitting useful data
25 even though the subscriber may only be analyzing one image
26 for some time.

27 However, should the user desire to zoom in on a
28 particular region of an image, he or she may define that
29 region desired on the terminal 20 by the Guided Image
30 Selection & Transmission (GIST) to expand the *visual display*
31 accordingly. The DCR will recognize the requirement for
32

1 additional resolution and command the PIE to begin
2 transmitting additional pixel information until such time as
3 the DCR informs it that once again the natural display
4 resolution limit has been reached.

5 The following image enhancement means present in the
6 instant invention: edge contrast enhancement, gray level
7 constrast enhancement by means of gray level region expansion
8 or differential gray level tracking and gray level
9 enhancement and may be accomplished by the image enhancing
10 processor means 139 in the visual display terminals 20.

11 The human eye cannot reliably discern gray level
12 differences less than approximately 2%. Yet, significant
13 tissue density information causes X-ray gray level
14 differences in this range and below. The enhancement
15 technologies above will cause these tissue density
16 differences to be magnified thus revealing hitherto unseen
17 image data.

18 To ensure ease of use, the following features are
19 incorporated: touch-screen selection of commands, magnetic
20 card identification of the subscriber or user, icon based
21 menus or selection buttons on the CRT display and split image
22 display screen overlays.

23 It will thus be seen that the objects set forth above,
24 among those made apparent from the preceding description are
25 efficiently attained and since certain changes may be made in
26 the above construction without departing from the scope of
27 the invention, it is intended that all matter contained in
28 the above description or shown in the accompanying drawing
29 shall be interpreted as illustrative and not in a limiting
30 sense.
31
32

1 It is also to be understood that the following claims
2 are intended to cover all of the generic and specific
3 features of the invention herein described, and all
4 statements of the scope of the invention which, as a matter
5 of language, might be said to fall therebetween.

6 Now that the invention has been described,
